

Programmable Money That Intercepts Itself

RemitStream: Cross-border remittances with auto-save & yield, built on Stellar and Soroban.

THE TRANSFER FRICTION

6–8%

Migrant workers lose 6–8% of every remittance to fees and wait days for settlement. Traditional rails cannot economically serve the standard \$20–50 weekly transfer pattern.

THE WEALTH DESTRUCTION

\$0 Savings

On the receiving end, capital is consumed instantly. Recipients in emerging markets are excluded from savings products, let alone yield-bearing assets.

Two problems, one transfer.
Getting the money there is **slow and expensive**.
Keeping any of it is nearly impossible.

The Prismatic Shift: In-Flight Value Routing

The Remittance Evolution Matrix

	Traditional (Western Union/Bank)	Standard Crypto (USDC on L1/L2)	RemitStream (Stellar + Soroban)
Settlement Time	1-3 Days	Seconds/Minutes	~5 Seconds
Average Fees	6-8%	Variable (\$0.01 - \$5.00+)	≈\$0.00001
Trustline Setup (UX Friction)	N/A (High fiat friction)	Required (High UX friction)	Zero (SEP-41 native)
Embedded Savings Mechanic	None	Manual (Secondary action)	Automatic (In-flight auto-split)
Yield Generation	None	Manual (DeFi staking)	Pro-Rata (Built-in vault)

The Auto-Split Router Engine

The recipient owns the rule. The sender cannot override the recipient's savings preference. Funds are withdrawable instantly, yield included.

Soroban Contract Architecture

- Responsibility: Splits incoming remittances based on user-defined rules.
- Function: Forwards spendable capital, pushes remainder to vault, tracks lifetime statistics.

- Responsibility: Manages the share-based yield generation.
- Function: Holds capital securely and dynamically updates balances based on pro-rata distributions.

- Responsibility: SEP-41 test stablecoin (rUSDC) engine.
- Function: Manages built-in rate-limited faucets. Balances live directly in contract storage—eliminating all trustline setup for pilot users.

Defensive Design & Contract Math

Sovereign Rules

set_rule requires the recipient's own signature.
A sender can never dictate how much someone else saves.

Self-Verifying Vaults

credit() re-checks the vault's actual token balance against accounted assets. A compromised router cannot mint shares out of thin air.

Solvency-First Rounding

Withdrawal share burn rounds up. The router's split truncates in the recipient's favor, ensuring payout + saved == amount, leaving zero residue.

Shallow Auth Trees

A single signature per remittance. The router pulls the full amount once and fans it out efficiently.

Non-Dilutive Yield Accrual

Share-Accounting Pro-Rata Mechanism

The Deposit (Shares Minted)

User deposits rUSDC, minting a fixed number of shares in the savings-vault.

Time Passes,
Yield Accrues

The Yield (Density Increases)

Yield is distributed by raising accounted assets without minting new shares. Every holder gains pro rata. Later deposits do not dilute existing holders.

Yield
Distribution

Frontend Engineering & UX

Next.js 16, React 19, Tailwind CSS. Typed contract clients vendored directly into `web/src/bindings` (no separate build step).

Live Split Preview: The sender sees exactly what the recipient will receive and save before confirming—quoted directly from the chain, not guessed.

Multi-Wallet & Error Handling: Native support for Freightier, xBull, Albedo, Lobstr. Error boundaries map contract panics via `humanizeError` into actionable sentences.

First-Party Telemetry & Monitoring

Complemented by [@vercel/analytics](#) for web vitals, all managed first-party.

The Sovereign Trustless Loop

Protocol Roadmap & Expansion
